### 2.1 Diffusion Models

Diffusion models are

Given observed datapoints  $\mathbf{x}$ , the goal of a generative model is to learn to model its true data distribution  $p(\mathbf{x})$ .

#### 2.1.1 Forward Diffusion Process

The *forward process* is a Gaussian diffusion process that defines a sequence of increasingly noisy versions of  $\mathbf{x}$ , which we call the *latent variables*:

$$\mathbf{z} = \{\mathbf{z}_t \mid t \in [0, 1]\} \quad (2.1)$$

The forward process forms a conditional joint distribution  $q(\mathbf{z}|\mathbf{x})$ , whose marginal distributions of latent variables  $\mathbf{z}_t$  given  $\mathbf{x} \sim p(\mathbf{x})$  are given by:

$$q(\mathbf{z}_t|\mathbf{x}) = \mathcal{N}(\mathbf{z}_t; \alpha_t \mathbf{x}, \sigma_t^2 \mathbf{I}) \quad (2.2)$$

where  $\alpha_t$  and  $\sigma_t$  are strictly positive scalar-valued functions of  $t$ .

A notable aspect of the forward process is that the joint distribution of latent variables  $\mathbf{z}_r, \mathbf{z}_s, \mathbf{z}_t$  at subsequent timesteps  $0 \leq r < s < t \leq 1$  is Markovian:

$$q(\mathbf{z}_t|\mathbf{z}_s, \mathbf{z}_r) = q(\mathbf{z}_t|\mathbf{z}_s) = \mathcal{N}(\mathbf{z}_t; \alpha_{t|s} \mathbf{z}_s, \sigma_{t|s}^2 \mathbf{I}) \quad (2.3)$$

where  $\alpha_{t|s} = \alpha_t \alpha_s^{-1}$  and  $\sigma_{t|s}^2 = \sigma_t^2 - \alpha_{t|s}^2 \sigma_s^2$ . A full derivation of  $q(\mathbf{z}_t|\mathbf{z}_s)$  is given in Appendix A.1.

#### 2.1.2 Noise Schedule

We formalise the notion that  $\mathbf{z}_t$  is increasingly noisy by defining the log signal-to-noise ratio

$$\lambda_t = \log \left( \frac{\alpha_t^2}{\sigma_t^2} \right) \in [\lambda_{\min}, \lambda_{\max}] \quad (2.4)$$

as a strictly monotonically decreasing function  $f_\lambda$  of time  $t \in [0, 1]$ , known as the *noise schedule*.

In this work, we use a truncated continuous-time version of the  $\alpha$ -cosine schedule [5], introduced in its original discrete-time form by Nichol and Dhariwal [5]. The  $\alpha$ -cosine schedule was motivated by the fact that the ‘linear’ schedule introduced in prior work by Ho et al. [1] causes  $\alpha_t$  to fall to zero more quickly than is optimal. Nichol and Dhariwal empirically found that this induces too much noise in the latter stages of the forward diffusion process; as such, the latent variables  $\mathbf{z}_t$  in these stages contribute little to sample quality. In response, they proposed the original discrete-time  $\alpha$ -cosine schedule. In this work, we use a continuous-time diffusion model and therefore use an adapted model described in [3]. More formally, we define:

$$f_\lambda(t) = -2 \log \left( \tan \left( \frac{\pi}{2} (t_0 + t(t_1 - t_0)) \right) \right) \quad (2.5)$$

where  $t_0$  and  $t_1$  truncate the range of  $f_\lambda(t)$  to  $[\lambda_{\min}, \lambda_{\max}]$  for  $t \in [0, 1]$ , and are themselves defined as:

$$t_0 = \frac{2}{\pi} \arctan \left( \exp \left( -\frac{1}{2} \lambda_{\max} \right) \right) \quad (2.6)$$

$$t_1 = \frac{2}{\pi} \arctan \left( \exp \left( -\frac{1}{2} \lambda_{\min} \right) \right) \quad (2.7)$$

We compute  $\alpha_t$  and  $\sigma_t$  from  $\lambda_t$  via the following equations:

$$\alpha_t = \sqrt{S(\lambda_t)} \quad (2.8)$$

$$\sigma_t = \sqrt{S(-\lambda_t)} \quad (2.9)$$

where  $S$  is the sigmoid function. A full derivation of  $f_\lambda$  is given in Appendix A.2.

### 2.1.3 Reverse Generative Model

The generative model is a learned hierarchical model that matches the forward process running in reverse-time: we sequentially generate latent variables  $\mathbf{z}_t$  starting from  $t = 1$  and working backwards to  $t = 0$ .

Assuming our diffusion model is variance preserving (i.e.  $\alpha_t^2 = 1 - \sigma_t^2$ ) and sufficiently small  $\lambda_{\min}$ , we can model the marginal distribution of  $\mathbf{z}_1$  as the multivariate standard Gaussian:

$$p(\mathbf{z}_1) \approx \mathcal{N}(\mathbf{z}_1; \mathbf{0}, \mathbf{I}) \quad (2.10)$$

In this work, to sequentially generate the latent variables, we use the discrete-time ancestral sampler [1]. We define:

$$p_\theta(\mathbf{z}_s | \mathbf{z}_t) = q(\mathbf{z}_s | \mathbf{z}_t, \mathbf{x} = \hat{\mathbf{x}}_\theta(\mathbf{z}_t, \lambda_t)) \quad (2.11)$$

$$= \mathcal{N} \left( \tilde{\boldsymbol{\mu}}_{s|t}(\mathbf{z}_t, \mathbf{x} = \hat{\mathbf{x}}_\theta(\mathbf{z}_t, \lambda_t)), \tilde{\sigma}_{s|t} \mathbf{I} \right) \quad (2.12)$$

where  $\hat{\mathbf{x}}_\theta(\mathbf{z}_t, \lambda_t)$  is our denoised estimate of the original data  $\mathbf{x}$  given latent  $\mathbf{z}_t$  and log signal-to-noise ratio  $\lambda_t$ , and

$$\tilde{\boldsymbol{\mu}}_{s|t}(\mathbf{z}_t, \mathbf{x}) = \frac{\alpha_{t|s} \sigma_s^2}{\sigma_t^2} \mathbf{z}_t + \frac{\alpha_s \sigma_{t|s}^2}{\sigma_t^2} \mathbf{x} \quad (2.13)$$

$$\tilde{\sigma}_{s|t}^2 = \frac{\sigma_{t|s} \sigma_s}{\sigma_t} \quad (2.14)$$

For large enough  $\lambda_{\max}$ ,  $\mathbf{z}_0$  is almost noiseless, so learning a model  $p(\mathbf{z}_0)$  is practically equivalent to learning a model  $p(\mathbf{x})$ .

### 2.1.4 Objective Function

Diffusion models in the literature are optimised with various objectives that are special cases of a weighted loss [4].

### A.1 Derivation of $q(\mathbf{z}_t|\mathbf{z}_s)$

From Equation 2.2, we know  $q(\mathbf{z}_t|\mathbf{x})$  is an isotropic Gaussian probability density function. As such, we can sample  $\mathbf{z}_t \sim q(\mathbf{z}_t|\mathbf{x})$  by sampling  $\boldsymbol{\epsilon}_t \sim \mathcal{N}(\mathbf{0}, \mathbf{I})$  from the multivariate standard Gaussian distribution and computing:

$$\mathbf{z}_t = \alpha_t \mathbf{x} + \sigma_t \boldsymbol{\epsilon}_t \quad (\text{A.1})$$

With some algebraic manipulation, we can show that:

$$\mathbf{z}_t = \alpha_t \mathbf{x} + \sqrt{\sigma_t^2} \boldsymbol{\epsilon}_t \quad (\text{A.2})$$

$$= \alpha_t \mathbf{x} + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2 + \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t \quad (\text{A.3})$$

$$= \alpha_t \mathbf{x} + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2 + \left(\frac{\alpha_t}{\alpha_s} \sigma_s\right)^2} \boldsymbol{\epsilon}_t \quad (\text{A.4})$$

The sum of two independent Gaussian random variables with mean  $\mu_1$  and  $\mu_2$  and variance  $\sigma_1^2$  and  $\sigma_2^2$  is a Gaussian random variable with mean  $\mu_1 + \mu_2$  and variance  $\sigma_1^2 + \sigma_2^2$ . As such, we can manipulate the above equation further to show that:

$$\mathbf{z}_t = \alpha_t \mathbf{x} + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t^* + \frac{\alpha_t}{\alpha_s} \sigma_s \boldsymbol{\epsilon}_s \quad (\text{A.5})$$

$$= \alpha_t \mathbf{x} + \frac{\alpha_t}{\alpha_s} \sigma_s \boldsymbol{\epsilon}_s + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t^* \quad (\text{A.6})$$

$$= \frac{\alpha_s}{\alpha_s} \alpha_t \mathbf{x} + \frac{\alpha_t}{\alpha_s} \sigma_s \boldsymbol{\epsilon}_s + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t^* \quad (\text{A.7})$$

$$= \frac{\alpha_t}{\alpha_s} (\alpha_s \mathbf{x} + \sigma_s \boldsymbol{\epsilon}_s) + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t^* \quad (\text{A.8})$$

$$(\text{A.9})$$

where  $\boldsymbol{\epsilon}_t^*, \boldsymbol{\epsilon}_s \sim \mathcal{N}(\mathbf{0}, \mathbf{I})$  are similarly both sampled from the multivariate standard Gaussian distribution. We can substitute  $\mathbf{z}_s = \alpha_s \mathbf{x} + \sigma_s \boldsymbol{\epsilon}_s$  into the above equation to show that:

$$\mathbf{z}_t = \frac{\alpha_t}{\alpha_s} \mathbf{z}_s + \sqrt{\sigma_t^2 - \frac{\alpha_t^2}{\alpha_s^2} \sigma_s^2} \boldsymbol{\epsilon}_t^* \quad (\text{A.10})$$

$$= \alpha_{t|s} \mathbf{z}_s + \sigma_{t|s} \boldsymbol{\epsilon}_t^* \quad (\text{A.11})$$

$$\sim \mathcal{N}(\mathbf{z}_t; \alpha_{t|s} \mathbf{z}_s, \sigma_{t|s}^2 \mathbf{I}) \quad (\text{A.12})$$

The subscript  $t|s$  relates to the fact that  $\alpha_{t|s}$  and  $\sigma_{t|s}$  define the parameters of the Gaussian probability density function  $q(\mathbf{z}_t|\mathbf{z}_s)$ .

## A.2 $\alpha$ -Cosine Noise Schedule

Before truncation, the continuous-time version of the  $\alpha$ -cosine schedule [5] as described in [3] defines  $\alpha_t^2$  at a given timestep  $t \in [0, 1]$  as:

$$\alpha_t^2 = \cos^2\left(\frac{\pi}{2}t\right) \quad (\text{A.13})$$

Since our model is a variance-preserving diffusion model, we can show that:

$$\sigma_t^2 = 1 - \alpha_t^2 \quad (\text{A.14})$$

$$= 1 - \cos^2\left(\frac{\pi}{2}t\right) \quad (\text{A.15})$$

$$= \sin^2\left(\frac{\pi}{2}t\right) \quad (\text{A.16})$$

As such, we define our noise schedule before truncation  $\tilde{f}_\lambda$  for all  $t \in [0, 1]$  as:

$$\tilde{f}_\lambda(t) = \log\left(\frac{\alpha_t^2}{\sigma_t^2}\right) \quad (\text{A.17})$$

$$= \log\left(\frac{\cos^2\left(\frac{\pi}{2}t\right)}{\sin^2\left(\frac{\pi}{2}t\right)}\right) \quad (\text{A.18})$$

$$= -2\log\left(\tan\left(\frac{\pi}{2}t\right)\right) \quad (\text{A.19})$$

However, the above noise schedule means that  $\tilde{f}_\lambda : [0, 1] \rightarrow [-\infty, \infty]$ ; in simpler terms,  $\lambda_t$  is unbounded. We follow prior work (e.g. [3, 2]) by truncating  $\lambda_t$  to the desired range  $[\lambda_{\min}, \lambda_{\max}]$ . To do so, we first need to define the inverse of the unbounded noise schedule:

$$\tilde{f}_\lambda^{-1}(\lambda) = \frac{2}{\pi} \arctan\left(\exp\left(-\frac{1}{2}\lambda\right)\right) \quad (\text{A.20})$$

From this, we define  $t_0$  and  $t_1$  as:

$$t_0 = \tilde{f}_\lambda^{-1}(0) = \frac{2}{\pi} \arctan\left(\exp\left(-\frac{1}{2}\lambda_{\max}\right)\right) \quad (\text{A.21})$$

$$t_1 = \tilde{f}_\lambda^{-1}(1) = \frac{2}{\pi} \arctan\left(\exp\left(-\frac{1}{2}\lambda_{\min}\right)\right) \quad (\text{A.22})$$

The truncated noise schedule used in this work is then defined as:

$$f_\lambda(t) = \tilde{f}_\lambda(t_0 + t(t_1 - t_0)) \quad (\text{A.23})$$

$$= -2\log\left(\tan\left(\frac{\pi}{2}(t_0 + t(t_1 - t_0))\right)\right) \quad (\text{A.24})$$
